Extracorporeal Membrane Oxygenation and Conventional Medical Therapy in Neonates With Persistent Pulmonary Hypertension of the Newborn: A Prospective Randomized Study

P. Pearl O’Rourke, MD, Robert K. Crone, MD, Joseph P. Vacanti, MD, James H. Ware, PhD, Craig W. Lillehei, MD, Richard B. Parad, MD, and Michael F. Epstein, MD

Placing ECMO Cannulae at the Bedside
Background to the Harvard Trial

- An RCT in the 1970s had shown ECMO not effective for ARDS in adults

- In the 1980s, Robert Bartlett used ECMO to treat newborns with PPHN

- Results were very impressive

- But, pediatricians were reluctant to adopt ECMO without convincing data from an RCT
Questions

• Imagine you were Bob Bartlett

• Would you have sought to perform an RCT to demonstrate the superiority of ECMO to Conventional Medical Therapy (CMT)?

• Why or why not?
Extracorporeal Circulation in Neonatal Respiratory Failure: A Prospective Randomized Study

Robert H. Bartlett, MD, Dietrich W. Roloff, MD, Richard G. Cornell, PhD, Alice French Andrews, MD, Peter W. Dillon, MD, and Joseph B. Zwischenberger, MD
Bartlett: Play-the-Winner Design

10 ECMO: survived
1 CMT: died
Questions

• Imagine you were a neonatologist in Boston

• When you read this article, would you have told your hospital administrator that you needed to start an ECMO program?

• Why or why not?
“The clinical indications for this new and complex treatment remain undefined. Further randomized controlled trials... will be difficult but remain necessary.”
Extracorporeal Membrane Oxygenation and Conventional Medical Therapy in Neonates With Persistent Pulmonary Hypertension of the Newborn: A Prospective Randomized Study

P. Pearl O’Rourke, MD, Robert K. Crone, MD, Joseph P. Vacanti, MD, James H. Ware, PhD, Craig W. Lillehei, MD, Richard B. Parad, MD, and Michael F. Epstein, MD
The Harvard Neonatal ECMO Trial
Randomized newborns with PPHN to conventional therapy versus ECMO

**Conventional Therapy**
- NICU: 7th Floor
- Neonatologists
- No patients had ever been offered ECMO
- Anti-ECMO

**ECMO**
- PICU: 5th Floor
- Anesthesiologists & Surgeons
- Already had experience with ECMO for newborns with CDH
- Pro-ECMO
The Harvard Neonatal ECMO Trial: Study Design

- Eligible newborns had PPHN and a predicted mortality of 85% based on retrospective data
- Phase I: 50/50 randomization until there were 4 deaths in one arm
- Phase II: Assign all patients to the more successful therapy, until there are 4 deaths in that arm or until statistical significance is achieved
- Seek consent only from those randomized to the experimental therapy
\[ P(p_1 > p_2) = \frac{F_1}{F_1 + F_2 + F_3}, \]
\[ P(p_1 = p_2) = \frac{F_2}{F_1 + F_2 + F_3}, \]
\[ P(p_1 < p_2) = \frac{F_3}{F_1 + F_2 + F_3}, \]

where

\[ F_1 = \int_0^1 \int_0^{p_1} p_1^{a-2}(1 - p_1)^{b-1} p_2^{b+3} (1 - p_1)^{p_2} \, dp_1 \, dp_2 \]
\[ = \int_0^1 p_1^{a+4}(1 - p_1)^{b+3} \int_0^{p_1} p_2^{b} \, dp_1 \, dp_2 \]
\[ = \frac{1}{10} \int_0^1 p_1^{a+14}(1 - p_1)^{b+3} \, dp_1 \]
\[ = \frac{1}{10} \frac{\Gamma(a + 15)\Gamma(b + 4)}{\Gamma(a + b + 19)} \]

and, similarly

\[ F_2 = \frac{\Gamma(a + 15)\Gamma(b + 4)}{\Gamma(a + b + 19)}, \]
\[ F_3 = \frac{1}{10} \left[ \frac{\Gamma(a + 6)\Gamma(b + 3)}{\Gamma(a + b + 9)} - \frac{\Gamma(a + 16)\Gamma(b + 3)}{\Gamma(a + b + 19)} \right]. \]

Healer versus Investigator

The Fundamental Conflict
The Fundamental Dilemma

• A dilemma confronts physician-investigators…

• As physicians they are dedicated to caring for their patients…

• As investigators they are dedicated to caring for their research…

• These two commitments conflict whenever an individual physician/investigator comes face to face with an individual patient/subject.  

Jay Katz, 1993
HIRAM S. DUDSON 1930 - 1993
Member, Placebo Group
Possible Solution #1: Full Separation of Roles

“Researchers must give patients stark, bold, and dramatic signs that research is different from clinical care… instead of the white coats associated with medical care, investigators could wear red ones…”

Possible Solution #2: Personal Equipoise

- Requires that the investigator be personally unbiased between the treatment arms, “perfectly balanced on the edge of the sword”

- But, researchers usually “believe in” the treatments they study

- Requiring personal equipoise leaves investigators feeling either “guilty” or “cynical”
Possible solution #3: Clinical Equipoise

• Requires uncertainty within the medical community as a whole
  • “I believe that “A” is better, but if your appointment had been with my colleague down the hall, she would have recommended “B”
  • “So… would you agree to have your treatment determined by a coin flip, so that we can learn from this experience?”

• Harvard ECMO Trial
  • Likely that no single investigator was in personal equipoise
  • Freedman: the collective uncertainty represented clinical equipoise

Adaptive Randomization

Balancing Conflicting Obligations
Adaptive Randomization

- Definition: Deviating from “balanced” or 50/50 randomization, with more patients assigned to the therapy that is “leading” during the trial

- Betting on the horse who is out in front, before we know how the race will end
Adaptive Randomization

• Attempts to minimize number of patients assigned to the less-successful therapy

• Attempts to mitigate the conflict of healer versus investigator
  • In the Bartlett trial, 50/50 randomization was guaranteed only for the first patient
  • In the Harvard trial, 50/50 randomization was guaranteed until the 4th death in one arm
Adaptive Randomization: Disadvantages

- There must be only one primary outcome of interest
- The outcome must be apparent within a short period of time
- May suffer from accrual bias: volunteers may want to be recruited into the trial later
The trial was criticized from both directions

- **No patients should have been assigned to CMT**
  
  “The clear expectation was that more patients would die on conventional therapy. Was having an excess number of deaths balanced by the worth of the information gained? My answer is a resounding no.”

  Don Berry, U of Minnesota

- **Not enough patients were assigned to CMT**
  
  The researchers were so preoccupied with ethical problems that they stopped the conventional therapy too soon.

  Colin Begg, Memorial Sloan Kettering

  “There is a slightly hysterical view that we need to stop a study as soon as we have an idea which treatment might be better.”

  Paul Meyer, U of Chicago

- **Perhaps this approach was a good balance**

I-SPY 2: An Adaptive Breast Cancer Trial Design in the Setting of Neoadjuvant Chemotherapy

AD Barker¹, CC Sigman², GJ Kelloff³, NM Hylton⁴, DA Berry⁴ and LJ Esserman³

I-SPY 2 (investigation of serial studies to predict your therapeutic response with imaging and molecular analysis 2) is a process targeting the rapid, focused clinical development of paired oncologic therapies and biomarkers. The framework is an adaptive phase II clinical trial design in the neoadjuvant setting for women with locally advanced breast cancer. I-SPY 2 is a collaborative effort among academic investigators, the National Cancer Institute, the US Food and Drug Administration, and the pharmaceutical and biotechnology industries under the auspices of the Foundation for the National Institutes of Health Biomarkers Consortium.

treatment options remain limited. These patients continue to represent a disproportionately large fraction of those who die of their disease. Given that the standard of care for these women increasingly includes neoadjuvant therapy prior to surgical resection, this combination of group and setting represents a unique opportunity to learn how to tailor the treatment to patients with high-risk breast cancers.

Cancer research from the past decade has shown that breast cancer is a number of heterogeneous diseases; this finding suggests that directing drugs to molecular pathways that characterize the disease in subsets of patients will improve treatment efficacy. Currently, however, most phase II and III trials of new

A Harvard study on newborns draws fire

Doctors faulted for limiting life-saving treatment

By Richard A. Knox
Globe Staff

A Harvard University study involving mortally ill newborns is being challenged as unethical in a debate that raises important questions about how to do research on promising new therapies.

Critics around the country are raising two kinds of objections to the still-unpublished Harvard study.

The study was unethical in the first place, some charge, because it involved withholding from some infants with lung damage potentially life-saving therapy that earlier, less scientifically rigorous data had indicated was probably superior to conventional treatment.

Four infants with potentially reversible lung damage died on conventional respirator therapy before the researchers stopped assigning babies to that alternative.

Second, critics say it was improper for the researchers not to seek consent from parents of the infants assigned to conventional therapy. Parents of 10 conventionally treated infants were not told their children were part of a randomized trial in which some babies would get the promising but possibly risky new treatment.

Parents of nine babies randomly assigned to the new treatment, called extracorporeal membrane oxygenation, or ECMO, were asked for their consent. All ECMO-treated babies survived.

"The clear expectation was that more patients would die on conventional therapy," statistician Donald A. Berry of the University of Minnesota, one of the study’s harshest critics, said in a telephone interview. "So the question is whether having an excess of deaths balances the worth of information gained. Since I believe such information is available without randomizing, my answer is a resounding no."

Prof. Richard M. Royall of the Johns Hopkins School of Public Health charged in an interview that once the Harvard researchers decided a randomized clinical trial was necessary, they had to "cut corners" on informed consent in order to proceed. "It’s clear to me they did not ask consent because it would be hard to get a control group otherwise," Royall said. "Properly informed parents would say ‘No thank you.’"

However, not all agree the study was unethical at the outset.

A second group, represented by Colin B. Begl of Memorial Sloan-Kettering Cancer Center in New York and Paul Meier of the University of Chicago, lambastes the Harvard researchers from the diametrically opposite side. They say the researchers were so preoccupied with ethical problems that they stopped assigning babies to conventional therapy too soon, before NEWBORNS. Page 27
The ECMO Trial: Justifications for Randomized Consent

- Control patients were not really research subjects
- Families of control patients were really not be offered a choice
  - "The decision was controversial among the team. We had several weeks of discussion over ‘autonomy’ versus ‘paternalism’" – Mike Epstein
  - “I’d prefer to call it ‘openness’ versus ‘compassion’” – Jim Ware
The Response to the ECMO Trial

• The NIH Office for Protection from Research Risks (OPRR) reprimanded the hospital

  • The hospital IRB “made decisions that rightfully belonged to the parents. They really blew it.”  
    Charles McCarthy, Director of OPRR

  • The doctors “were doing exactly what physicians did before we had a doctrine of informed consent - making decisions for parents.”  
    George Annas, Boston University
Are RCTs the only way to learn?
Approaches to Learning: Ascending Order of Confidence

- Meta-analyses
- Randomized Controlled Trials
- Case / Control Observational Studies
- Databases
- Case Series with Historical Controls
- Case Series with Literature Controls
- Case Series without Controls
- Anecdotal Case Reports
Are RCTs the only way to learn?

• “The brilliant success of the RCT has now become a form of intellectual tyranny”  
  Freireich

• “We should not proceed on the fallacious assumption that where there is no randomization, there is no truth.”  
  Royall
Conclusions
We found little evidence that estimates of treatment effects in observational studies reported after 1984 are either consistently larger than or qualitatively different from those obtained in randomized, controlled trials. (N Engl J Med 2000;342:1878-86.)
We should abandon randomized controlled trials in the intensive care unit

Jean-Louis Vincent, MD, PhD, FCCM

The randomized controlled trial is seen by many as the summit of evidence-based medicine, yet, in the intensive care unit, randomized controlled trials can be challenging to conduct, and results are often difficult to interpret and apply. Many randomized controlled trials in intensive care patients have not demonstrated beneficial effects of the intervention under investigation often despite good preclinical and even previous randomized controlled trial evidence. There are many reasons for these negative results including problems with timing, end point selection, and heterogeneous populations. In this article, we will discuss the limitations of randomized controlled trials in the intensive care unit population and highlight the importance of considering other study designs in the challenging intensive care unit environment. (Crit Care Med 2010; 38[Suppl.]:S534–S538)

“I will argue that in many situations with the ICU context, the RCT as we know it should be abandoned, at least temporarily, and much greater emphasis be placed on gathering information from well-designed observational studies.”
Data published in 1988

- ECMO database of 715 newborns treated with ECMO (no controls)
- These patients had an 81% survival
- ECMO statistically superior to any other treatment with a survival rate less than 78.4%
Question

- Given all you’ve seen, are you now convinced that ECMO is superior to conventional therapy?
The existing “RCTs of neonatal ECMO… suggested reductions in mortality but were not conclusive.”

Because they “used adaptive designs, which may have introduced bias…”

Field et al. UK collaborative randomised trial of neonatal extracorporeal membrane oxygenation. Lancet 1996;348:75-82
The UK Neonatal ECMO Trial

- 1993-1995: 185 neonates randomized to ECMO vs CMT
- Trial stopped early by DSMB,
  - ECMO survival 60/93 = 65%
  - CMT survival 38/92 = 41%, p<0.0005
- Were 22 babies unnecessarily “sacrificed”? 
Conclusions

• RCTs are usually the best approach for evaluating new therapies, but…

• The conflict between clinician and investigator is profound and can never be entirely eliminated

• Adaptive randomization is one way to balance the competing obligations

• Zelen randomization reduces the psychological burdens of the investigators, but is probably unacceptable
Conclusions

"The use of statistics in medical research has been compared to a religion: it has its high priests (statisticians), supplicants (journal editors and researchers), and orthodoxy (for example, p<.05 is “significant”)

Benjamin Freedman
“Never, ever, think outside the box”
